

Lecture #27: Scheme Examples

- A little philosophy: why are we talking about interpreters, etc.?
- Idea is to understand your programming language better by understanding common concepts in the design of programming languages
- ... And also to get better mental models of what programs are doing by actually studying how a program might be executed.
- With this, you can perhaps develop better intuitions about what usages are likely to be expensive.
- More directly, many projects can benefit from the introduction of specialized "little languages" and studying interpreters gives you some background in defining and implementing them.

Tail-Recursive Length?

Last time, we came up with this:

```
;; The length of list L
(define (length L)
  (if (eqv? L '())          ; Alternative: (null? L)
      0
      (+ 1 (length (cdr L)))))
```

but this is not tail recursive. How do we make it so?

Tail-Recursive Length: Solution

```
;; The length of list L
(define (length L)
  ;; n + the length of R.
  (define (length+ n R)
    (if (null? R) n
        (length+ (+ n 1) (cdr R))))
  (length+ 0 L))
```

Standard List Searches: `assoc`, etc.

- The functions `assq`, `assv`, and `assoc` classically serve the purpose of Python dictionaries.
- An *association list* is a list of key/value pairs. The Python dictionary `{1 : 5, 3 : 6, 0 : 2}` might be represented

`((1 . 5) (3 . 6) (0 . 2))`

- The `assx` functions access this list, returning the pair whose `car` matches a key argument.
- The difference between the methods is whether we use `eq?` (Python is), `eqv?` (more like Python `==`), or `equal?` (does "deep" comparison of lists).

```
;; The first item in L whose car is eqv? to key, or #f if none.  
(define (assv key L)  
)
```

Assv Solution

;; The first item in L whose car is eqv? to key, or #f if none.

```
(define (assv key L)
  (cond ((null? L)                #f)
        ((eqv? key (caar L)) (car L))
        (else                  (assv key (cdr L))))
)
```

- Why `caar`?

- L has the form `((key1 . val1) (key2 . val2) ...)`.
- So the `car` of L is `(key1 . val1)`, and its key is therefore `(car (car L))` (or `caar` for short).

A classic: reduce

```
;; Assumes f is a two-argument function and L is a list.  
;; If L is (x1 x2...xn), the result of applying f n-1 times  
;; to give (f (f (... (f x1 x2) x3) x4) ...).  
;; If L is empty, returns f with no arguments.  
;; [Simply Scheme version.]  
;; >>> (reduce + '(1 2 3 4)) ==> 10  
;; >>> (reduce + '()) ==> 0  
(define (reduce f L)  
  
)
```

Reduce Solution (1)

```
;; Assumes f is a two-argument function and L is a list.
;; If L is (x1 x2...xn), the result of applying f n-1 times
;; to give (f (f (... (f x1 x2) x3) x4) ...).
;; If L is empty, returns f with no arguments.
(define (reduce f L)
  (cond ((null? L)
        (f))      ; Odd case with no items
        ((null? (cdr L))
         (car L)) ; One item
        )
    (else
     (reduce f (cons (f (car L) (cadr L))
                     (cddr L))))

; E.g.:
; (reduce + '(2 3 4))
; -calls-> (reduce + (5 4))
; -calls-> (reduce + (9))
; -yields-> 9
```

Reduce Solution (2)

```
;; Assumes f is a two-argument function and L is a list.  
;; If L is (x1 x2...xn), the result of applying f n-1 times  
;; to give (f (f (... (f x1 x2) x3) x4) ...).  
;; If L is empty, returns f with no arguments.  
(define (reduce f L)  
  (define (reduce-tail accum R)  
    (cond ((null? R) accum)  
          (else (reduce-tail (f accum (car R)) (cdr R)))))  
  
  (if (null? L) (f)      ;; Special case  
      (reduce-tail (car L) (cdr L))))
```
