Lecture #13: More Sequences and Strings

Odds and Ends: Multi-Argument Map

 Python's built-in map function actually applies a function to one or more sequences:

```
>>> from operator import *
>>> tuple(map(abs, (-1, 2, -4, 5))
(1, 2, 4, 5)
>>> tuple(map(add, (1, 2, 3, 18), (5, 2, 1)))
(6, 4, 4)
```

- That is, map takes a function of N arguments plus N sequences and applies the function to the corresponding items of the sequences (throws away extras, like 18).
- So, how do we do this:

```
def deltas(L):
    """Given that L is a sequence of N items, return
    the (N-1)-item sequence (L[1]-L[0], L[2]-L[1],...)."""
    return map(sub, tuple(L)[1:], L)
```

Defining multi-argument map: zip and F(*S)

CS61A: Lecture #13 1

• Defining map requires

Last modified: Man Feb 24 13:42:52 2014

- The library function zip:

```
>>> tuple(zip((1, 2), (3, 4), (5, 6, 7))) ((1, 3, 5), (2, 4, 6))
```

- And Python's "apply" and multi-argument syntax:

```
>>> def multi_arg(*args): print(args)
>>> multi_arg()
[]
>>> multi_arg(1)
[1]
>>> multi_arg(3, 4, 5)
[3, 4, 5]
>>> def two_argument_function(x, y): return 2*x + 3*y
>>> two_argument_function(3, 4)
18
>>> two_argument_function( *(3, 4) )
18
>>> two_argument_function( *(3, 4) )
18
odef map(func, *sequences):
    return (func(*S) for S in zip(*sequences))
```

Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 3

Odds and Ends: Membership

• Built-in Python sequences support the membership operation:

```
>>> 5 in (2, 3, 5, 7, 11, 13, 17, 19)
True
>>> 6 not in (2, 3, 5, 7, 11, 13, 17, 19)
True
>>> (3, 2) in ((1, 2), (3, 4), (6, 5), (2, 3))
False
>>>
```

CS61A: Lecture #13 4

Representing Multi-Dimensional Structures

- How do we represent a two-dimensional table (like a matrix)?
- Answer: use a sequence of sequences (such as a tuple of tuples).
- The same approach is used in C, C++, and Java.
- Example:

$$\begin{bmatrix} 1 & 2 & 0 & 4 \\ 0 & 1 & 3 & -1 \\ 0 & 0 & 1 & 8 \end{bmatrix}$$

becomes

```
((1, 2, 0, 4), (0, 1, 3, -1), (0, 0, 1, 8))
# or
[[1, 2, 0, 4], [0, 1, 3, -1], [0, 0, 1, 8]]
```

The Game of Life: Another Problem

- J. H. Conway's Game of Life is an example of a *cellular automaton* on an infinite grid of squares.
- Each square may be occupied or unoccupied.
- \bullet One genertion of cells is computed from the preceding according to a simple rule:
 - An occupied empty square with 2 or 3 occupied neighbor squares in one generation remains occupied in the next.
 - An empty square with exactly 3 occupied neighbor squares in one generation becomes occupied in the next.
 - All other squares become or remain unoccupied in the next generation.
- One can build arbitrary computations from these simple rules, resulting in remarkable patterns.
- (See http://www.youtube.com/watch?v=C2vgICfQawE)

Counting Neighbors

- Consider the problem of computing the number of occupied neighbors of each cell on a grid.
- We'll use a slight modification: a finite grid that wraps around: the top row is adjacent to the bottom, and the left column adjacent to the right.
- Example (1 indicates occupancy; blank squares are 0):

Board											
		1	1	1							
		1	1	1							
		1		1							
		1			1	1					
					1	1					

Neighbor Count										
0	2	3	5	3	2	0	0			
0	3	4	7	4	3	0	0			
0	2	2	5	2	2	0	0			
0	2	2	3	2	3	2	1			
0	1	0	1	2	3	3	2			
0	1	1	1	2	3	3	2			
0	0	0	0	1	2	2	1			
0	1	2	3	2	1	0	0

CS61A: Lecture #13 7

CS61A: Lecture #13 9

Strategy (I): Map2

 Suppose that we have a function like map that operates on sequeuces of sequeuces.

• With this, we can find the number of neighbors of each cell (with a little help).

Last modified: Mon Feb 24 13:42:52 2014

CS61A: Lecture #13 8

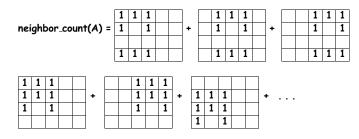

Strategy (II): rotate2

- \bullet $\it Rotating$ a sequence right by N means moving its last N values to the front, shifting the rest over.
- ullet Rotating left by N moves the first N values to the end.
- We rotate 2D lists in two directions: rotating the rows and the columns:

```
def rotate2(A, dr, dc):
    """Given that A is a 2-dimensional sequence the result of rotating each
    row of A by DC columns and each column by DR rows. That is, a new
    2D tuple, B, in which B[r+dr][c+dc] is A[r][c], wrapping at the ends.
    >>> rotate2( ((1, 2, 3), (4, 5, 6), (7, 8, 9), (10, 11, 12)), (1, -1))
    ((11, 12, 10), (2, 3, 1), (5, 6, 4), (8, 9, 7))"""
    def rotate(R, d):
        # Negative slice indices count from the right.
        if d < 0:
            return R[-len(R)-d:] + R[0: -d]
        else:
            return R[-d:] + R[0: len(R)-d]
    rows = tuple(map(lambda row: rotate(row, dc), A))
    return rotate(rows, dr)</pre>
```

Strategy (III): Adding Up Neighbors

 Now we can find number of neighbors (with wrap-around) by shifting and adding:

Last modified: Mon Feb 24 13:42:52 2014

CS61A: Lecture #13 10

Finally, neighbor_count

Putting it all together:

Last modified: Mon Feb 24 13:42:52 2014

```
def neighbor_count(A):
    """Given a life board A, the number of neighbors corresponding to each
   cell as a tuple of tuples, assuming the board wraps around.
   >>> neighbor_count(((0, 0, 0, 0),
                       (0, 1, 0, 0),
                       (0, 1, 1, 0),
                       (0, 0, 0, 0)))
    ((1, 1, 1, 0), (2, 2, 3, 1), (2, 2, 2, 1), (1, 2, 2, 1))
    sum2 = lambda A, B: map2(add, A, B)
   neighbors = ((-1, -1), (-1, 0), (-1, 1),
                (0, -1),
                                   (0, 1),
                (1, -1), (1, 0), (1, 1))
   return reduce(sum2,
                 map(lambda d: rotate2(A, d[0], d[1]),
                     neighbors))
```

Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 11

Strings: A Specialized Type of Sequence

- Strings are sequences of characters, with a good deal of special syntax.
- Rather odd property: the base cases are circular. Characters are themselves strings of length 1!
- The usual operations on tuples apply also to strings:

Last modified: Mon Feb 24 13:42:52 2014

CS61A: Lecture #13 12

Modified Operations

• Membership is not quite the same for strings:

```
>>> 'b' in ('a', 'b', 'c', 'd')  # A sequence, not a string
True
>>> 'bc' in ('a', 'b', 'c', 'd')
False
# But...
>>> 'b' in 'abcd'
True
>>> 'bc' in 'abcd'  # in Finds substrings
```

 The substring is generally more important than the character, in other words.

Last modified: Man Feb 24 13:42:52 2014

CS61A: Lecture #13 13

Numerous Functions and Methods

 The calls str(x) and x._str_() convert values of any type into strings that depict them:

• The methods reflect common manipulations from "real life":

```
>>> "i can't find my shift key".capitalize()
'I can't find my shift key'.capitalize()
>>> "cHaNge".upper() + " CaSe".lower() + " raNDomLY".swapcase()
'CHANGE case RAndOMly'
>>> '1234'.isnumeric() and 'abcd'.isalpha()
True
>>> 'SNAKEeyes'.upper().endswith('YES')
True
>>> '{x} + {y} = {answer}'.format(answer=7, x=3, y=4)
'3 + 4 = 7'
>>> " ".join(map(lambda x: x.capitalize(), "a bunch of words".sp'A Bunch Of Words'
```

Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 14

A Cast of Thousands

- Python3 uses Unicode as its basic character set: an international standard comprising most alphabets (dead and alive).
- Characters have standard numbers (indicating position in the character set) and names. The Python ord and chr convert from character to number and back.
- Getting your computer to actually render them all properly, however, is another matter entirely, which is outside Python.
- The character codes from 0-127 (7-bit codes) are known as ASCII (American Standard Code for Information Interchange). Everything you typically type uses this subset.
- Nice property: 1 byte (8 bits) per character.
- This is lost with Unicode, but since there is an extra bit, we can encode larger character codes (UTF-8).

CS61A: Lecture #13 15

Denoting Characters and Strings

 You've seen string literals all along. Python has 8 (!) styles. Consider the string

```
\begin{quote}
"I'd rather be in Philadelphia."
\end{quote}
```

which we can write:

```
>>> "\begin{quote}\n\"I'd rather be in Philadelphia.\"\n\\end{quote}"
>>> '\begin{quote}\n"I'd rather be in Philadelphia."\n\\end{quote}'
>>> """\begin{quote}
... "I'd rather be in Philadelphia."
... \\end{quote}""
>>> '''\\begin{quote}
... "I'd rather be in Philadelphia."
... \\end{quote}""
>>> '"'\begin{quote}
... "I'd rather be in Philadelphia."
... \\end{quote}""
>>> r"""\begin{quote}
... "I'd rather be in Philadelphia."
... \\end{quote}""
```

Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 16

Escapes

- \bullet The \backslash escape allows us to introduce special, non-graphical characters" newline $\backslash n$, tab $\backslash t$
- Or to insert quoting characters.
- Or Unicode characters:

 $\label{local_u03b1} $$ u03b1\u03b2\u03b3\u03b6\u05d1\u05d0\u8071\u8072$$ "\u263a\u2639"$

[Try printing this on your home computer].

Strings as Sequences

- Most string operations are variations on the sequence operations we've seen.
- \bullet Example: take a string, break it into lines, indent the lines by N spaces, glue the lines back together, and return the result

• Use it to indent a file:

Last modified: Mon Feb 24 13:42:52 2014

```
print(indent_lines(open("afile").read(), 4))
```

• An even more general manipulation: regular expressions:

```
import re
def indent_lines(s, n):
    return re.sub(r'(?m)^', ' ' * n, a)
```

Further exploration left to the reader. E.g., see 13.py

Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 17

CS61A: Lecture #13 18

• Python 3 defines map, reduce, and filter on sequences just as we did on rlists. ullet So to compute the sum of the even Fibonacci numbers among the first 12 numbers of that sequence, we could proceed like this: First 20 integers: 0 1 2 3 4 5 6 7 8 9 10 11 Map fib: 0 1 1 2 3 5 8 13 21 34 55 89 Filter to get even numbers: 0 2 8 34 Reduce to get sum: 44 reduce(add, filter(is_even, map(fib, range(12)))) • Why is this important? Sequences are amenable to parallelization. Last modified: Mon Feb 24 13:42:52 2014 CS61A: Lecture #13 19

Observation: Sequences as Conventional Interfaces
