61A Lecture 31

Wednesday, November 20

Announcements

- •Project 4 due Thursday 11/21 @ 11:59pm.
- •Extra reader office hours in 405 Soda this week.
 - •Wednesday: 5:30pm-7pm
 - -Thursday: 5:30pm-7pm
- Homework 10 due Tuesday 11/26 @ 11:59pm.
- •Recursive art contest entries will be due Monday 12/2 @ 11:59pm (After Thanksgiving).

Databases

A table is a collection of records, which are tuples of values organized in columns.

Databases store tables and have have methods for adding, editing, and retrieving records.

The Structured Query Language (SQL) is perhaps the most widely used programming language.

SELECT * FROM toy_info WHERE color='yellow';

toy_id toy	color	cost	weight					
2 whiffleba	ll yellow	2.20	0.40	Fach	row	is	а	record
5 frisbee	yellow	1.50	0.20	Lacii	100	13	<u>u</u>	
10 yoyo	yellow	1.50	0.20					

SQL is an example of a declarative programming language.

It separates what to compute from how it is computed.

The language interpreter is free to compute the result in any way it wants.

Declarative Programming

Characteristics of declarative languages:

- •A "program" is a description of the desired solution.
- The interpreter figures out how to generate such a solution.

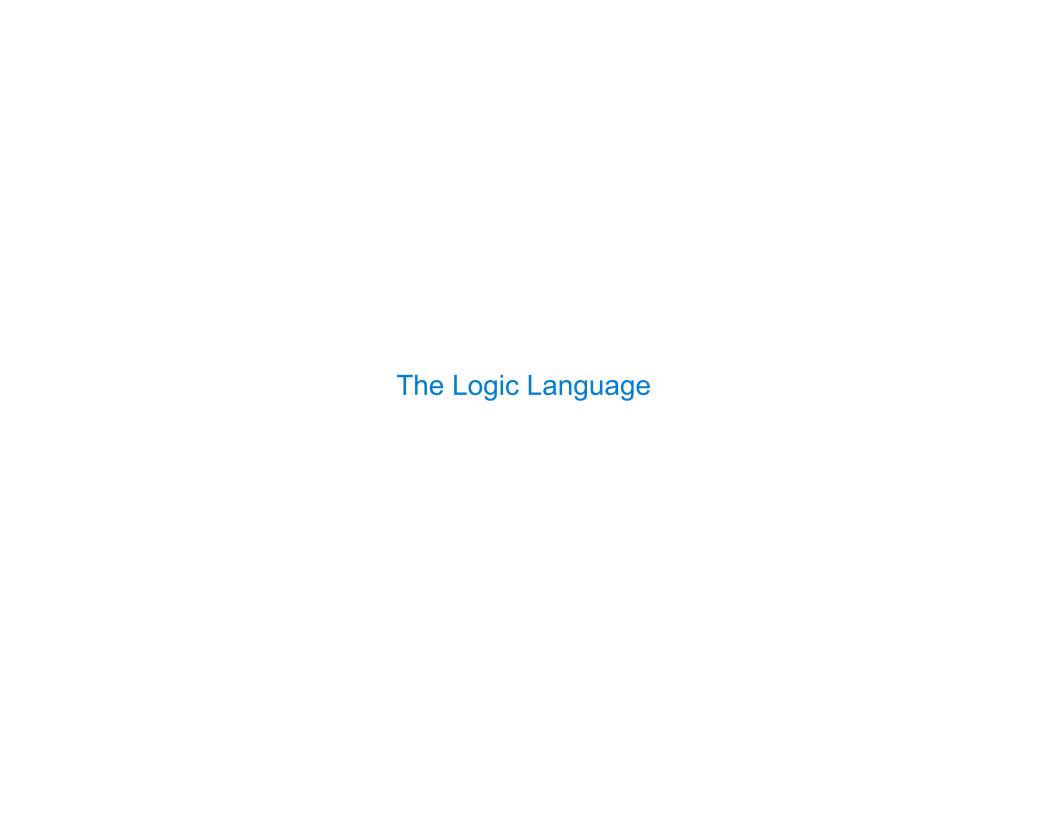

In imperative languages such as Python & Scheme:

- •A "program" is a description of computational processes.
- The interpreter carries out execution and evaluation rules.

Building a universal problem solver is hard.

Declarative languages often handle only some subset of problems.

The Logic Language

The Logic language is invented for this course.

- Based on the Scheme project with ideas from Prolog (1972).
- Expressions are facts or queries, which contain relations.
- Expressions and relations are Scheme lists.
- For example, (likes john dogs) is a relation.
- Implementation fits on a single sheet of paper (next lecture).

Today's theme:

Simple Facts

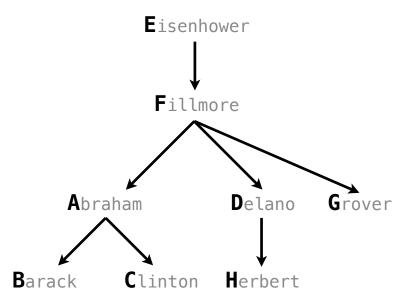

A simple fact expression in the Logic language declares a relation to be true.

Let's say I want to track the heredity of a pack of dogs.

Language Syntax:

- •A relation is a Scheme list.
- •A fact expression is a Scheme list of relations.

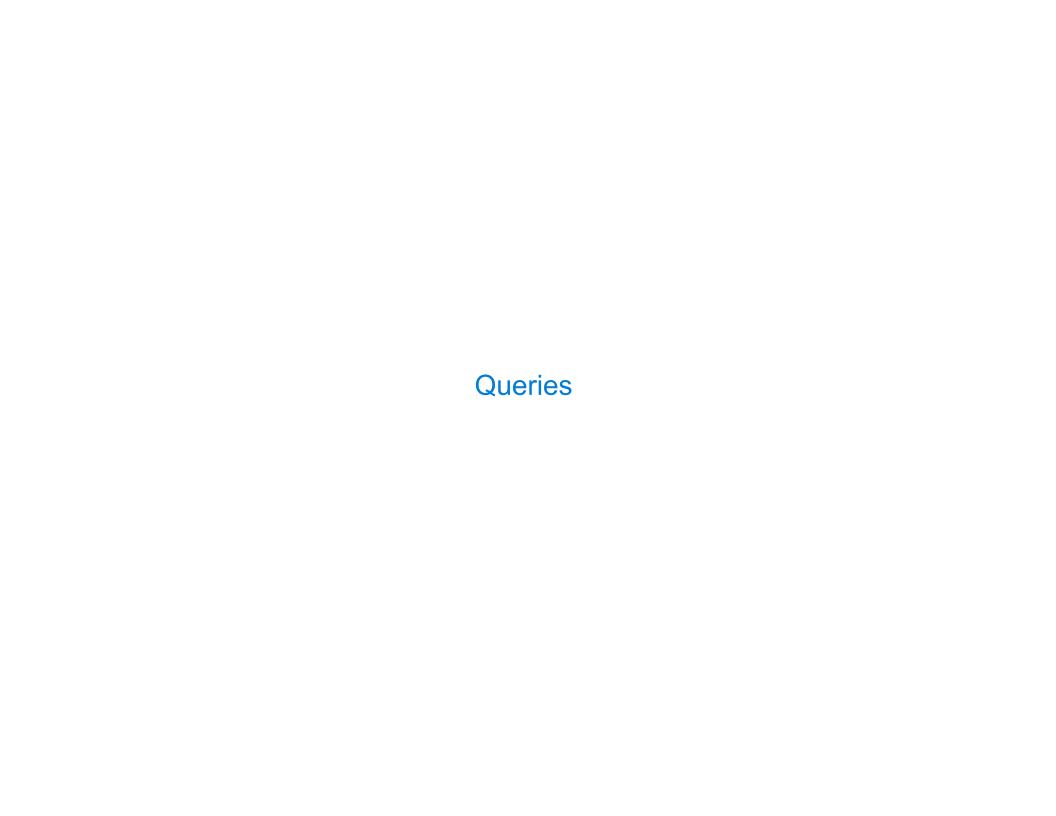

```
logic> (fact (parent delano herbert))
logic> (fact (parent abraham barack))
logic> (fact (parent abraham clinton))
logic> (fact (parent fillmore abraham))
logic> (fact (parent fillmore delano))
logic> (fact (parent fillmore grover))
logic> (fact (parent eisenhower fillmore))
```

Relations are Not Procedure Calls

```
In Logic, a relation is not a call expression.
• Scheme: the expression (abs -3) calls abs on -3. It returns 3.
• Logic: (abs -3 3) asserts that abs of -3 is 3.

To assert that 1 + 2 = 3, we use a relation: (add 1 2 3)
We can ask the Logic interpreter to complete relations based on known facts.
```

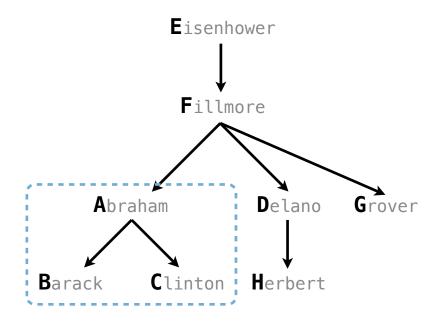

Queries

A query contains one or more relations that may contain variables.

Variables are symbols starting with $oldsymbol{?}$

```
logic> (fact (parent delano herbert))
logic> (fact (parent abraham barack))
logic> (fact (parent abraham clinton))
logic> (fact (parent fillmore abraham))
logic> (fact (parent fillmore delano))
logic> (fact (parent fillmore grover))
logic> (fact (parent eisenhower fillmore))
logic> (query (parent abraham ?puppy))
Success!
puppy: barack
                            A variable can
                            have any name
puppy: clinton
 Each line is an assignment
   of variables to values
                                        (Demo)
```

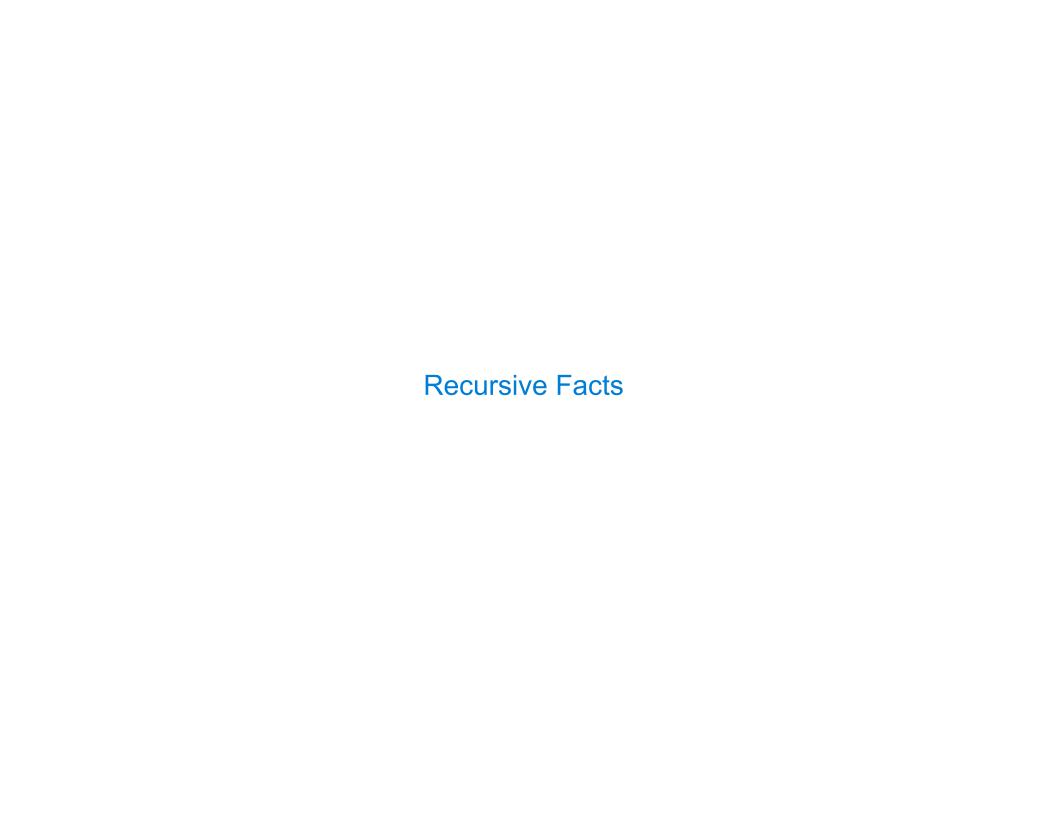

Compound Facts and Queries

Compound Facts

```
A fact can include multiple relations and variables as well.
    (fact <conclusion> <hypothesis_0> <hypothesis_1> \dots <hypothesis_N>)
Means <conclusion> is true if all the <hypothesis<sub>K</sub>> are true.
logic> (fact (child ?c ?p) (parent ?p ?c))
                                                               Eisenhower
logic> (query (child herbert delano))
Success!
                                                                Fillmore
logic> (query (child eisenhower clinton))
Failure.
logic> (query (child ?kid fillmore))
Success!
                                                        Abraham
                                                                       Delano
                                                                                Grover
kid: abraham
kid: delano
kid: grover
                                                   Barack
                                                             Clinton Herbert
```

Compound Queries

```
An assignment must satisfy all relations in a query.
               (query <relation<sub>0</sub>> <relation<sub>1</sub>> ... <relation<sub>N</sub>>)
is satisfied if all the <relation <> are true.
logic> (fact (child ?c ?p) (parent ?p ?c))
                                                                Eisenhower
logic> (query (parent ?grampa ?kid)
               (child clinton ?kid))
Success!
                                                                 Fillmore
grampa: fillmore kid: abraham
logic> (query (child ?y ?x)
               (child ?x eisenhower))
                                                         Abraham
                                                                        Delano
                                                                                 Grover
Success!
y: abraham
              x: fillmore
y: delano
               x: fillmore
               x: fillmore
y: grover
                                                   Barack
                                                              Clinton
                                                                       Herbert
```

Recursive Facts

A fact is recursive if the same relation is mentioned in a hypothesis and the conclusion.

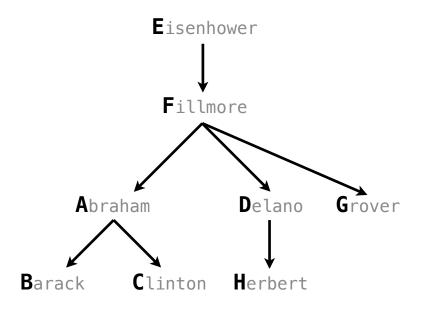

```
logic> (fact (ancestor ?a ?y) (parent ?a ?y))
logic> (fact (ancestor ?a ?y) (parent ?a ?z) (ancestor ?z ?y))

logic> (query (ancestor ?a herbert))
Success!
a: delano
a: fillmore
a: eisenhower

Fir

Success!
a: fillmore
a: eisenhower

Abraham
Abraham
```

Searching to Satisfy Queries

The Logic interpreter performs a search in the space of relations for each query to find satisfying assignments.

```
logic> (query (ancestor ?a herbert))
Success!
a: delano
a: fillmore 
a: eisenhower
logic> (fact (parent delano herbert))
logic> (fact (parent fillmore delano))
logic> (fact (ancestor ?a ?y) (parent ?a ?y))
logic> (fact (ancestor ?a ?y) (parent ?a ?z) (ancestor ?z ?y))
(parent delano herbert)  ; (1), a simple fact
(ancestor delano herbert)  ; (2), from (1) and the 1st ancestor fact
(parent fillmore delano)  ; (3), a simple fact
(ancestor fillmore herbert) ; (4), from (2), (3), & the 2nd ancestor fact
```

Hierarchical Facts

Relations can contain relations in addition to symbols.

```
logic> (fact (dog (name abraham) (color white)))
logic> (fact (dog (name barack) (color tan)))
logic> (fact (dog (name clinton) (color white)))
logic> (fact (dog (name delano) (color white)))
logic> (fact (dog (name eisenhower) (color tan)))
logic> (fact (dog (name fillmore) (color gray)))
logic> (fact (dog (name grover) (color tan)))
logic> (fact (dog (name herbert) (color gray)))
Variables can refer to symbols or whole relations.
logic> (query (dog (name clinton) (color ?color)))
                                                                      D
                                                                             G
Success!
color: white
logic > (query (dog (name clinton) ?stats))
Success!
                                                         B
stats: (color white)
```

Combining Multiple Data Sources

Which dogs have an ancestor of the same color?
